

Specification of Source §3 Non-Det—2021 edition

Martin Henz, Arsalan Cheema, Anubhav

National University of Singapore
School of Computing

July 14, 2021

The language Source is the official language of the textbook *Structure and Interpretation of Computer Programs, JavaScript Adaptation*. Source is a sublanguage of ECMAScript 2018 (9th Edition) and defined in the documents titled “Source §*x*”, where *x* refers to the respective textbook chapter.

Source §3 Non-Det is a nondeterministic variant of Source §3.

1 Changes

Source §3 Non-Det modifies Source §3 by adding an automatic search mechanism into the language semantics. The language allows programmers to specify *choices* and *requirements*. At runtime, the search mechanism automatically resolves these requirements, and identifies all those choices that satisfy them.

This is achieved by supporting a new type of expression, called the *choice point* expression. Every choice point expression is described by a (possibly empty) set of *expressions* (known as the set of *choices*). At runtime, a choice point expression can assume any value from its set of choices. A program can also include instructions that force the language processor to *backtrack* to any choice point expression. *Backtracking* means that the choice point expression will take on a different value from its set of choices, and the program will then be re-evaluated with this new choice.

A Source §3 Non-Det program can contain any number of choice points. Evaluating a program can hence have an exponential number of outcomes - one outcome for every combination of possible choices. The language’s search mechanism, however, only returns one outcome at a time. The programmer can *command* the search mechanism to re-evaluate the program with a different combination of choices. On the Source Academy Playground, this command is implemented as the magic phrase `try_again`, which has to be entered into the REPL.

In the Source Academy implementation, the Source §3 Non-Det evaluator can only process one program at a time. If the evaluator is given a new program **before** all the outcomes of an existing program have been processed, then all remaining outcomes will be ignored.

Unlike the implementations of Source §3, the implementation of Source §3 Non-Det does not use a constant amount of memory for loops. Instead, memory usage increases linearly with the number of iterations. This is because each iteration can be nondeterministic. Each iteration’s state must be kept in memory so that the language processor can backtrack to every iteration. Similarly, no tail call optimization is done, because every function application’s state must be kept in memory to allow backtracking.

Source §3 Non-Det currently does not support import directives.

2 Syntax

A Source program is a *program*, defined using Backus-Naur Form¹ as follows:

¹ We adopt Henry Ledgard’s BNF variant that he described in *A human engineered variant of BNF*, ACM SIGPLAN Notices, Volume 15 Issue 10, October 1980, Pages 57-62. In our grammars, we use **bold** font for keywords, *italics* for

<i>program</i> ::= <i>statement</i> ...	program
<i>statement</i> ::= const <i>name</i> = <i>expression</i> ;	constant declaration
let ;	variable declaration
<i>assignment</i> ;	variable assignment
<i>expression</i> [<i>expression</i>] = <i>expression</i> ;	array assignment
function <i>name</i> (<i>parameters</i>) <i>block</i>	function declaration
return <i>expression</i> ;	return statement
<i>if-statement</i>	conditional statement
while (<i>expression</i>) <i>block</i>	while loop
for ((<i>assignment</i> <i>let</i>);	
<i>expression</i> ;	
<i>assignment</i>) <i>block</i>	for loop
break ;	break statement
continue ;	continue statement
<i>block</i>	block statement
<i>expression</i> ;	expression statement
<i>parameters</i> ::= ϵ <i>name</i> (, <i>name</i>) ...	function parameters
<i>if-statement</i> ::= if (<i>expression</i>) <i>block</i>	
[else (<i>block</i> <i>if-statement</i>)]	conditional statement
<i>block</i> ::= { <i>statement</i> ... }	block statement
<i>let</i> ::= let <i>name</i> = <i>expression</i>	variable declaration
<i>assignment</i> ::= <i>name</i> = <i>expression</i>	variable assignment
<i>expression</i> ::= <i>number</i>	primitive number expression
true false	primitive boolean expression
<i>string</i>	primitive string expression
null	primitive list expression
<i>name</i>	name expression
<i>expression</i> <i>binary-operator</i> <i>expression</i>	binary operator combination
<i>unary-operator</i> <i>expression</i>	unary operator combination
<i>expression</i> (<i>expressions</i>)	function application
(<i>name</i> (<i>parameters</i>)) => <i>expression</i>	lambda expression (expr. body)
(<i>name</i> (<i>parameters</i>)) => <i>block</i>	lambda expression (block body)
<i>expression</i> ? <i>expression</i> : <i>expression</i>	conditional expression
<i>expression</i> [<i>expression</i>]	array access
[<i>expressions</i>]	literal array expression
(<i>expression</i>)	parenthesised expression
<i>binary-operator</i> ::= + - * / % === !==	
> < >= <= &&	binary operator
<i>unary-operator</i> ::= ! -	unary operator
<i>expressions</i> ::= ϵ <i>expression</i> (, <i>expression</i>) ...	argument expressions

Restrictions

- Return statements are only allowed in bodies of functions.
- There cannot be any newline character between **return** and *expression* in return statements.²
- There cannot be any newline character between (*name* | (*parameters*)) and **=>** in function definition expressions.³
- Implementations of Source are allowed to treat function declaration as **syntactic sugar for constant declaration**.⁴ Source programmers need to make sure that functions are not called before their corresponding function declaration is evaluated.

Import directives

Import directives allow programs to import values from modules and bind them to names, whose scope is the entire program in which the import directive occurs. Import directives can only appear at the top-level. All names that appear in import directives must be distinct, and must also be distinct from all top-level variables. The Source specifications do not specify how modules are programmed.

Binary boolean operators

Conjunction

*expression*₁ **&&** *expression*₂

stands for

*expression*₁ ? *expression*₂ : **false**

Disjunction

*expression*₁ **||** *expression*₂

stands for

*expression*₁ ? **true** : *expression*₂

Loops

while-loops

Roughly speaking, while loops are seen as abbreviations for function applications as follows:

while (*expression*) *block*

stands for

```
function _body() { block }
_while( () => expression , _body );
```

where `_while` is defined as follows:

```
function _while(test, body) {
  if (test()) {
    body();
    _while(test, body);
  } else {
    undefined;
  }
}
```

² Source inherits this syntactic quirk of JavaScript.

³ditto

⁴ECMAScript prescribes “hoisting” of function declarations to the beginning of the surrounding block. Programs that rely on this feature will run fine in JavaScript but might encounter a runtime error “Cannot access name before initialization” in a Source implementation.

Simple for-loops

for (*assignment*₁ ; *expression* ; *assignment*₂) *block*

stands for

```

assignment1
while (expression) {
    block
    assignment2
}

```

for-loops with loop control variable

for (**let** *name* = *expression*₁ ; *expression*₂ ; *assignment*) *block*

stands for

```

{
    let name = expression1;
    for (name = name; expression2; assignment) {
        const _copy_of_name = name;
        {
            const name = _copy_of_name;
            block
        }
    }
}

```

Return values, break and continue

Contrary to the simplified explanation above, **while** and **for** loops return the value of their last loop execution, or *undefined* if there is no loop execution. Evaluation of a **break** statement within a loop terminates the loop with the return value *undefined* and evaluation of a **continue** statement within a loop terminates the current loop iteration and evaluates the test.

Names

Names⁵ start with `_`, `$` or a letter⁶ and contain only `_`, `$`, letters or digits⁷. Restricted words⁸ are not allowed as names.

Valid names are `x`, `_45`, `$$` and `π`, but always keep in mind that programming is communicating and that the familiarity of the audience with the characters used in names is an important aspect of program readability.

Numbers

We use decimal notation for numbers, with an optional decimal dot. “Scientific notation” (multiplying the number with 10^x) is indicated with the letter `e`, followed by the exponent *x*. Examples for numbers are 5432, -5432.109, and -43.21e-45.

⁵ In [ECMAScript 2020 \(9th Edition\)](#), these names are called *identifiers*.

⁶ By *letter* we mean [Unicode](#) letters (L) or letter numbers (NI).

⁷ By *digit* we mean characters in the [Unicode](#) categories Nd (including the decimal digits 0, 1, 2, 3, 4, 5, 6, 7, 8, 9), Mn, Mc and Pc.

⁸ By *restricted word* we mean any of: `arguments`, `await`, `break`, `case`, `catch`, `class`, `const`, `continue`, `debugger`, `default`, `delete`, `do`, `else`, `enum`, `eval`, `export`, `extends`, `false`, `finally`, `for`, `function`, `if`, `implements`, `import`, `in`, `instanceof`, `interface`, `let`, `new`, `null`, `package`, `private`, `protected`, `public`, `return`, `static`, `super`, `switch`, `this`, `throw`, `true`, `try`, `typeof`, `var`, `void`, `while`, `with`, `yield`. These are all words that cannot be used without restrictions as names in the strict mode of ECMAScript 2020.

Strings

Strings are of the form "*double-quote-characters*", where *double-quote-characters* is a possibly empty sequence of characters without the character " and without the newline character, of the form '*single-quote-characters*', where *single-quote-characters* is a possibly empty sequence of characters without the character ' and without the newline character, and of the form '*backquote-characters*', where *backquote-characters* is a possibly empty sequence of characters without the character '. Note that newline characters are allowed as *backquote-characters*.

The following characters can be represented in strings as given:

- horizontal tab: \t
- vertical tab: \v
- nul char: \0
- backspace: \b
- form feed: \f
- newline: \n
- carriage return: \r
- single quote: \'
- double quote: \"
- backslash: \\

Unicode characters can be used in strings using \u followed by the hexadecimal representation of the unicode character, for example '\uD83D\uDC04'.

Arrays

Arrays in Source are created using literal array expressions:

```
let my_array_1 = [];
let my_array_2 = [42, 71, 13];
```

Comments

In Source, any sequence of characters between "/*" and the next "*/" is ignored. After "/*" any characters until the next newline character is ignored.

3 Dynamic Type Checking

Expressions evaluate to numbers, boolean values, strings, arrays or function values. Implementations of Source generate error messages when unexpected values are used as follows.

Only function values can be applied using the syntax:

$$expression ::= name(expressions)$$

For compound functions, implementations need to check that the number of *expressions* matches the number of parameters.

The following table specifies what arguments Source's operators take and what results they return. Implementations need to check the types of arguments and generate an error message when the types do not match.

operator	argument 1	argument 2	result
+	number	number	number
+	string	string	string
-	number	number	number
*	number	number	number
/	number	number	number
%	number	number	number
===	any	any	bool
!==	any	any	bool
>	number	number	bool
>	string	string	bool
<	number	number	bool
<	string	string	bool
>=	number	number	bool
>=	string	string	bool
<=	number	number	bool
<=	string	string	bool
&&	bool	any	any
	bool	any	any
!	bool		bool
-	number		number

Preceding `?` and following `if`, Source only allows boolean expressions.

In array access `arr[key]`, only arrays are allowed as `arr` and only integers are allowed as `key`.

Array indices in Source are limited to integers i in the range $0 \leq i < 2^{32} - 1$.

Pairs in Source are represented by arrays with two elements. Therefore,

```
is_pair([1, 2]);
```

and

```
equal(pair(1, 2), [1, 2]);
```

evaluate to `true`.

Access of an array with an array index to which no prior assignment has been made on the array returns `undefined`.

4 Standard Libraries

The following libraries are always available in this language.

MISC Library

The following names are provided by the MISC library:

- `get_time()`: *primitive*, returns number of milliseconds elapsed since January 1, 1970 00:00:00 UTC
- `parse_int(s, i)`: *primitive*, interprets the *string* `s` as an integer, using the positive integer `i` as radix, and returns the respective value, see [ECMAScript Specification, Section 18.2.5](#).
- `undefined`, `NaN`, `Infinity`: *primitive*, refer to JavaScript's `undefined`, `NaN` ("Not a Number") and `Infinity` values, respectively.
- `is_boolean(x)`, `is_number(x)`, `is_string(x)`, `is_undefined(x)`, `is_function(x)`: *primitive*, returns `true` if the type of `x` matches the function name and `false` if it does not. Following JavaScript, we specify that `is_number` returns `true` for `NaN` and `Infinity`.
- `prompt(s)`: *primitive*, pops up a window that displays the *string* `s`, provides an input line for the user to enter a text, a "Cancel" button and an "OK" button. The call of `prompt` suspends execution of the program until one of the two buttons is pressed. If the "OK" button is pressed, `prompt` returns the entered text as a string. If the "Cancel" button is pressed, `prompt` returns a non-string value.

- `display(x)`: *primitive*, displays the value x in the console⁹; returns the argument x .
- `display(x, s)`: *primitive*, displays the string s , followed by a space character, followed by the value x in the console⁹; returns the argument x .
- `error(x)`: *primitive*, displays the value x in the console⁹ with error flag. The evaluation of any call of `error` aborts the running program immediately.
- `error(x, s)`: *primitive*, displays the string s , followed by a space character, followed by the value x in the console⁹ with error flag. The evaluation of any call of `error` aborts the running program immediately.
- `stringify(x)`: *primitive*, returns a string that represents⁹ the value x .

All library functions can be assumed to run in $O(1)$ time, except `display`, `error` and `stringify`, which run in $O(n)$ time, where n is the size (number of components such as pairs) of their first argument.

MATH Library

The following names are provided by the MATH library:

- `math_name`, where *name* is any name specified in the JavaScript Math library, see [ECMAScript Specification, Section 20.2](#). Examples:
 - `math_PI`: *primitive*, refers to the mathematical constant π ,
 - `math_sqrt(n)`: *primitive*, returns the square root of the *number* n .

All functions can be assumed to run in $O(1)$ time and are considered *primitive*.

Nondeterminism support

The following primitives and builtins are supported:

- `amb(e1, e2, ..., en)`: *primitive*, creates a choice point whose value is chosen, at run-time, from the set $e1, e2, \dots, en$. Note: although the usage of this primitive syntactically resembles a function application, *amb* is not a function value. It is simply an operator, like the binary and unary operators. The values from the set $(e1, e2, \dots, en)$ are chosen sequentially, from left-to-right.
- `amb()`: applying *amb* without any arguments forces the language processor to backtrack to the most recent *amb expression*.
- `ambR(e1, e2, ..., en)`: *primitive*, creates a choice point. This is similar to *amb*, but the values from the set $(e1, e2, \dots, en)$ are chosen randomly and not sequentially.
- `cut()`: *primitive*, prevents the language processor from backtracking any further beyond the current statement. Note: *cut* is also not a function value. It is simply an operator, like the binary and unary operators.
- `require(pred)`: *builtin*, forces the language processor to backtrack to the most recent *amb expression*, if and only if *pred* is false.
- `an_element_of(xs)`: *builtin*, nondeterministically returns an element from the list *xs*.
- `an_integer_between(n, m)`: *builtin*, nondeterministically returns an integer between integers n and m (inclusively).
- `implication(p, q)`: *builtin* returns true if and only if the boolean values p and q satisfy the equation $P \Rightarrow Q$
- `bi_implication(p, q)`: *builtin* returns true if and only if the boolean values p and q satisfy the equation $P \Leftrightarrow Q$

⁹The notation used for the display of values is consistent with [JSON](#), but also displays `undefined` and function objects.

List Support

The following list processing functions are supported:

- `pair(x, y)`: *primitive*, makes a pair from `x` and `y`.
- `is_pair(x)`: *primitive*, returns `true` if `x` is a pair and `false` otherwise.
- `head(x)`: *primitive*, returns the head (first component) of the pair `x`.
- `tail(x)`: *primitive*, returns the tail (second component) of the pair `x`.
- `is_null(xs)`: *primitive*, returns `true` if `xs` is the empty list `null`, and `false` otherwise.
- `is_list(x)`: Returns `true` if `x` is a list as defined in the lectures, and `false` otherwise. Iterative process; time: $O(n)$, space: $O(1)$, where n is the length of the chain of `tail` operations that can be applied to `x`.
- `list(x1, x2, ..., xn)`: *primitive*, returns a list with n elements. The first element is `x1`, the second `x2`, etc. Iterative process; time: $O(n)$, space: $O(n)$, since the constructed list data structure consists of n pairs, each of which takes up a constant amount of space.
- `draw_data(x1, x2, ..., xn)`: *primitive*, visualizes each `x1, x2, ..., xn` in a separate drawing area in the Source Academy using a box-and-pointer diagram; time, space: $O(n)$, where n is the combined number of data structures such as pairs in `x1, x2, ..., xn`.
- `equal(x1, x2)`: Returns `true` if both have the same structure with respect to `pair`, and the same numbers, boolean values, functions or empty list at corresponding leaf positions (places that are not themselves pairs), and `false` otherwise; time, space: $O(n)$, where n is the number of pairs in `x`.
- `length(xs)`: Returns the length of the list `xs`. Iterative process; time: $O(n)$, space: $O(1)$, where n is the length of `xs`.
- `map(f, xs)`: Returns a list that results from list `xs` by element-wise application of `f`. Recursive process; time: $O(n)$, space: $O(n)$, where n is the length of `xs`.
- `build_list(n, f)`: Makes a list with n elements by applying the unary function `f` to the numbers 0 to $n - 1$. Recursive process; time: $O(n)$, space: $O(n)$.
- `for_each(f, xs)`: Applies `f` to every element of the list `xs`, and then returns `true`. Iterative process; time: $O(n)$, space: $O(1)$, where n is the length of `xs`.
- `list_to_string(xs)`: Returns a string that represents list `xs` using the text-based box-and-pointer notation [...].
- `reverse(xs)`: Returns list `xs` in reverse order. Iterative process; time: $O(n)$, space: $O(n)$, where n is the length of `xs`. The process is iterative, but consumes space $O(n)$ because of the result list.
- `append(xs, ys)`: Returns a list that results from appending the list `ys` to the list `xs`. Recursive process; time: $O(n)$, space: $O(n)$, where n is the length of `xs`.
- `member(x, xs)`: Returns first postfix sublist whose head is identical to `x` (==); returns `[]` if the element does not occur in the list. Iterative process; time: $O(n)$, space: $O(1)$, where n is the length of `xs`.
- `remove(x, xs)`: Returns a list that results from `xs` by removing the first item from `xs` that is identical (==) to `x`. Recursive process; time: $O(n)$, space: $O(n)$, where n is the length of `xs`.
- `remove_all(x, xs)`: Returns a list that results from `xs` by removing all items from `xs` that are identical (==) to `x`. Recursive process; time: $O(n)$, space: $O(n)$, where n is the length of `xs`.
- `filter(pred, xs)`: Returns a list that contains only those elements for which the one-argument function `pred` returns `true`. Recursive process; time: $O(n)$, space: $O(n)$, where n is the length of `xs`.

- `enum_list(start, end)`: Returns a list that enumerates numbers starting from `start` using a step size of 1, until the number exceeds ($>$) `end`. Recursive process; time: $O(n)$, space: $O(n)$, where n is the length of `xs`.
- `list_ref(xs, n)`: Returns the element of list `xs` at position `n`, where the first element has index 0. Iterative process; time: $O(n)$, space: $O(1)$, where n is the length of `xs`.
- `accumulate(op, initial, xs)`: Applies binary function `op` to the elements of `xs` from right-to-left order, first applying `op` to the last element and the value `initial`, resulting in r_1 , then to the second-last element and r_1 , resulting in r_2 , etc, and finally to the first element and r_{n-1} , where n is the length of the list. Thus, `accumulate(op, zero, list(1, 2, 3))` results in `op(1, op(2, op(3, zero)))`. Recursive process; time: $O(n)$, space: $O(n)$, where n is the length of `xs`, assuming `op` takes constant time.

Pair Mutators

The following pair mutator functions are supported:

- `set_head(p, x)`: *primitive*, changes the pair `p` such that its head is `x`. Returns undefined.
- `set_tail(p, x)`: *primitive*, changes the pair `p` such that its tail is `x`. Returns undefined.

Array Support

The following array processing functions are supported:

- `array_length(x)`: *primitive*, returns the current length of array `x`, which is 1 plus the highest index `i` that has been used so far in an array assignment on `x`.
- `is_array(x)`: *primitive*, returns `true` if `x` is an array, and `false` if it is not.

Stream Support

The following stream processing functions are supported:

- `stream_tail(x)`: *primitive*, assumes that the tail (second component) of the pair `x` is a nullary function, and returns the result of applying that function.
Laziness: Yes: `stream_tail` only forces the direct tail of a given stream, but not the rest of the stream, i.e. not the tail of the tail, etc.
- `stream(x1, x2, ..., xn)`: *primitive*, returns a stream with n elements. The first element is `x1`, the second `x2`, etc.
Laziness: No: In this implementation, we generate first a complete list, and then a stream using `list_to_stream`.
- `is_stream(x)`: Returns `true` if `x` is a stream as defined in the lectures, and `false` otherwise.
Laziness: No: `is_stream` needs to force the given stream.
- `list_to_stream(xs)`: transforms a given list to a stream.
Laziness: Yes: `list_to_stream` goes down the list only when forced.
- `stream_to_list(s)`: transforms a given stream to a list.
Laziness: No: `stream_to_list` needs to force the whole stream.
- `stream_length(s)`: Returns the length of the stream `s`.
Laziness: No: The function needs to force the whole stream.
- `stream_map(f, s)`: Returns a stream that results from stream `s` by element-wise application of `f`.
Laziness: Yes: The argument stream is only explored as forced by the result stream.
- `build_stream(n, f)`: Makes a stream with n elements by applying the unary function `f` to the numbers 0 to $n - 1$.
Laziness: Yes: The result stream forces the applications of `fun` for the next element.

- `stream_for_each(f, s)`: Applies `f` to every element of the stream `s`, and then returns `true`.
Laziness: No: `stream_for_each` forces the exploration of the entire stream.
- `stream_reverse(s)`: Returns finite stream `s` in reverse order. Does not terminate for infinite streams.
Laziness: No: `stream_reverse` forces the exploration of the entire stream.
- `stream_append(xs, ys)`: Returns a stream that results from appending the stream `ys` to the stream `xs`.
Laziness: Yes: Forcing the result stream activates the actual append operation.
- `stream_member(x, s)`: Returns first postfix substream whose head is equal to `x` (`===`); returns `null` if the element does not occur in the stream.
Laziness: Sort-of: `stream_member` forces the stream only until the element is found.
- `stream_remove(x, s)`: Returns a stream that results from given stream `s` by removing the first item from `s` that is equal (`===`) to `x`. Returns the original list if there is no occurrence.
Laziness: Yes: Forcing the result stream leads to construction of each next element.
- `stream_remove_all(x, s)`: Returns a stream that results from given stream `s` by removing all items from `s` that are equal (`===`) to `x`.
Laziness: Yes: The result stream forces the construction of each next element.
- `stream_filter(pred, s)`: Returns a stream that contains only those elements for which the one-argument function `pred` returns `true`.
Laziness: Yes: The result stream forces the construction of each next element. Of course, the construction of the next element needs to go down the stream until an element is found for which `pred` holds.
- `enum_stream(start, end)`: Returns a stream that enumerates numbers starting from `start` using a step size of 1, until the number exceeds (`>`) `end`.
Laziness: Yes: Forcing the result stream leads to the construction of each next element.
- `integers_from(n)`: Constructs an infinite stream of integers starting at a given number `n`.
Laziness: Yes: Forcing the result stream leads to the construction of each next element.
- `eval_stream(s, n)`: Constructs the list of the first `n` elements of a given stream `s`.
Laziness: Sort-of: `eval_stream` only forces the computation of the first `n` elements, and leaves the rest of the stream untouched.
- `stream_ref(s, n)`: Returns the element of stream `s` at position `n`, where the first element has index 0.
Laziness: Sort-of: `stream_ref` only forces the computation of the first `n` elements, and leaves the rest of the stream untouched.

Deviations from JavaScript

We intend the Source language to be a conservative extension of JavaScript: Every correct Source program should behave *exactly* the same using a Source implementation, as it does using a JavaScript implementation. We assume, of course, that suitable libraries are used by the JavaScript implementation, to account for the predefined names of each Source language. This section lists some exceptions where we think a Source implementation should be allowed to deviate from the JavaScript specification, for the sake of internal consistency and esthetics.

Evaluation result of programs: JavaScript statically distinguishes between *value-producing* and *non-value-producing statements*. All declarations are non-value-producing, and all expression statements, conditional statements and assignments are value-producing. A block is value-producing if its body statement is value-producing, and then its value is the value of its body statement. A sequence is value-producing if any of its component statements is value-producing, and then its value is the value of its *last* value-producing component statement. The value of an expression statement is the value of the expression. The value of a conditional statement is the value of the branch that gets executed, or the value `undefined`

if that branch is not value-producing. The value of an assignment is the value of the expression to the right of its `=` sign. Finally, if the whole program is not value-producing, its value is the value `undefined`.

Example 1:

```
1;  
{  
  // empty block  
}
```

The result of evaluating this program in JavaScript is 1.

Example 2:

```
1;  
{  
  if (true) {} else {}  
}
```

The result of evaluating this program in JavaScript is `undefined`.

Implementations of Source are currently allowed to opt for a simpler scheme.

Hoisting of function declarations: In JavaScript, function declarations are “hoisted” (automagically moved) to the beginning of the block in which they appear. This means that applications of functions that are declared with function declaration statements never fail because the name is not yet assigned to their function value. The specification of Source does not include this hoisting; in Source, function declaration can be seen as syntactic sugar for constant declaration and lambda expression. As a consequence, application of functions declared with function declaration may fail in Source if the name that appears as function expression is not yet assigned to the function value it is supposed to refer to.

Appendix: List library

Those list library functions that are not primitive functions are pre-declared as follows:

```
// list.js START

/**
 * makes a pair whose head (first component) is <CODE>x</CODE>
 * and whose tail (second component) is <CODE>y</CODE>.
 * @param {value} x - given head
 * @param {value} y - given tail
 * @returns {pair} pair with <CODE>x</CODE> as head and <CODE>y</CODE> as tail.
 */
function pair(x, y) {}

/**
 * returns <CODE>true</CODE> if <CODE>x</CODE> is a
 * pair and false otherwise.
 * @param {value} x - given value
 * @returns {boolean} whether <CODE>x</CODE> is a pair
 */
function is_pair(x) {}

/**
 * returns head (first component) of given pair <CODE>p</CODE>
 * @param {pair} p - given pair
 * @returns {value} head of <CODE>p</CODE>
 */
function head(p) {}

/**
 * returns tail (second component of given pair <CODE>p</CODE>
 * @param {pair} p - given pair
 * @returns {value} tail of <CODE>p</CODE>

Appendix: Nondeterminism library

Those nondeterminism functions that are not primitives are pre-declared as follows:

```
// non-det.js START

/**
 * Given <CODE>n</CODE> values, creates a choice point whose value is chosen,
 * at run-time, from the set <CODE>e1, e2, ..., en</CODE>.<br>
 * If <CODE>n</CODE> is 0, it forces the language processor to backtrack to
 * the most recent <CODE>amb</CODE> expression without returning a value.
 * @param {value} e1,e2,...en - given values
 * @returns {value} a value from the given values chosen sequentially
 */
function amb(e1, e2, ...en) {}

/**
 * Given <CODE>n</CODE> values, creates a choice point whose value is chosen,
 * at run-time, randomly from the set <CODE>e1, e2, ..., en</CODE>.<br>
 * If <CODE>n</CODE> is 0, it forces the language processor to backtrack to
 * the most recent <CODE>amb</CODE> expression without returning a value.<br>
 * Functions similarly to the <CODE>amb</CODE> operator but makes choices randomly
 * instead of sequentially.
 * @param {value} e1,e2,...en - given values
 * @returns {value} a value from the given values chosen randomly
 */
function ambR(e1, e2, ...en) {}

/**
 * Prevents the language processor from backtracking any further
 * beyond the current statement.
 */
